## 14 Abstract

15 We report detailed observations of K-leaders and the activity between them with  
 16 the three-dimensional Broadband Interferometric Mapping and Polarization system (BIMAP-  
 17 3D) at Los Alamos National Laboratory. It is found that K-leaders have a general prop-  
 18 agation trend of initial acceleration and then gradual deceleration, and the correspond-  
 19 ing very high frequency (VHF) radiation power is exponentially correlated with the leader  
 20 speed. Based on the 3D development and simultaneous electric field change measurement,  
 21 some simple K-leaders can be modeled with time-evolving point charges at the propa-  
 22 gating leader tip and at the stationary origin. We found that the charge magnitude in-  
 23 creases during the initial acceleration stage and stays relatively constant for the rest of  
 24 the development. K-leaders are observed to interact with other branches; the branches  
 25 affect the leader’s propagation speed, and may affect the charge transfer. After the oc-  
 26 currence of a K-leader, VHF emissions are quenched for several milliseconds. VHF sources  
 27 then reappear in an impulsive and scattered manner as “twinkling”, and these sources  
 28 are found not uniquely on the so-called needles, but also on the main channel. These twin-  
 29 kling sources start near the apparent positive leader tip, and extend back towards the  
 30 direction of the flash origin at about  $10^5$  m/s, while the apparent positive tip continues  
 31 to extend forward at about  $10^4$  m/s. The twinkling extending towards the direction of  
 32 flash origin appears to initiate the following K-leader, although it may be interrupted  
 33 by a K-leader along a different branch, or simply die out without more K-leader activ-  
 34 ity.

## 35 Plain Language Summary

36 A K-leader is a discharge process that occurs at the later stage of a lightning flash.  
 37 It retraces the path established by earlier discharges and propagates at a high speed of  
 38  $10^6$ - $10^7$  m/s. Recently we developed a new system called BIMAP-3D that can map light-  
 39 ning radio sources in 3D at a spatial resolution of 10 meters and at a time resolution of  
 40 a fraction of a microsecond. We found that K-leaders commonly speed up from  $10^6$  to  
 41  $10^7$  m/s at the initial stage and then gradually slow down to a stop at their later stage,  
 42 with associated radio power positively correlated with the traveling speed. Other branches  
 43 in the lightning flash are found to affect the K-leader speed as it approaches and passes  
 44 the branch junctions due to charge redistribution caused by the earlier processes. Af-  
 45 ter the occurrence of a K-leader radio emissions are shut off for a few milliseconds due  
 46 to the increased conductivity of the leader. After that, scattered radio sources reappear  
 47 in an expanding region, both extending the branch and expanding back towards the start-  
 48 ing point of the lightning. These apparent twinkling radio sources lead to the start of  
 49 the next K-leader.

## 50 1 Introduction

51 A K-leader is a lightning discharge process that retraces previously ionized chan-  
 52 nels in a lightning flash, at speeds on the order of  $10^7$  m/s (Schonland et al., 1935; Loeb,  
 53 1966; Jordan et al., 1992; Shao et al., 1995; Shao & Krehbiel, 1996; Stock et al., 2014).  
 54 K-leaders begin on a channel in the positive breakdown region (typically with net nega-  
 55 tive cloud charge density) and propagate in the direction of the negative breakdown re-  
 56 gion (Shao et al., 1995; Stock et al., 2014; Jensen et al., 2021). They are occasionally ob-  
 57 served turning “backwards” and propagating back down a different branch in the pos-  
 58 itive breakdown direction (Stock et al., 2014; Shao et al., 2018, 2023). Recent high speed  
 59 video observations for occasional out-of-cloud K-leader processes showed that K-leaders  
 60 start near but not at the tips of the positive breakdown channels (Mazur, 2016; Ding et  
 61 al., 2022). Very high frequency (VHF) radio observations show a similar initiation lo-  
 62 cation (Hare et al., 2021; Jensen et al., 2021). K-leaders have been observed to commonly  
 63 slow down as they propagate (Jordan et al., 1992; Stock et al., 2014; Jensen et al., 2021;

64 Hare et al., 2023), but sometimes to speed up for some fraction of their duration (Stock  
 65 et al., 2014; Jensen et al., 2021; Hare et al., 2023). The mechanisms behind the changes  
 66 of speed are not well understood, although Shao and Krehbiel (1996) reported that a K-  
 67 leader which had a burst of activity near its starting point apparently renewed and in-  
 68 tensified the breakdown activity at the negative end.

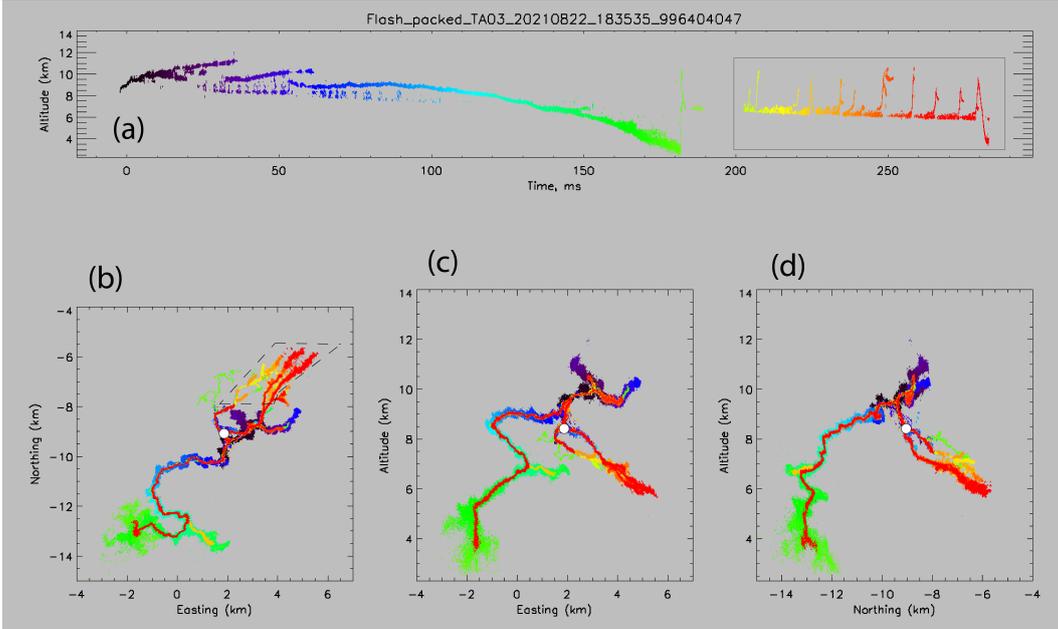

69 K-leaders are associated with an electric field change called a K-change (Kitagawa,  
 70 1957). Winn et al. (2011) compared New Mexico Tech’s Lightning Mapping Array (LMA)  
 71 observations with a balloon-borne electric field change measurement, and suggested that  
 72 the field change is related to a relatively higher charge concentration at the propagat-  
 73 ing leader tip. In this study the field change will be examined against the 3D K-leader  
 74 development to better understand the charge distribution along the channel while the  
 75 leader is propagating forward.

76 The process of K-leader initiation is even less well understood than the details of  
 77 K-leader development and dynamics. K-leaders are observed to start in the positive break-  
 78 down region, but unlike K-leaders themselves positive leaders are quiet at VHF and dif-  
 79 ficult to map (Shao et al., 1999; Edens et al., 2012; Pu et al., 2021; Stock et al., 2023).  
 80 VHF observations by Hare et al. (2019;2021) in this region have been attributed primar-  
 81 ily to other processes such as needles around the channel rather than to the actual posi-  
 82 tive leader tips. High speed video observations have provided insight into K-leader ini-  
 83 tiation and development when it occurs outside of the cloud. All of these optical obser-  
 84 vations show evidence of channel cutoff prior to K-leader initiation. That is, at the time  
 85 when the K-leader becomes visible the connecting channel structure is optically dark,  
 86 suggesting the channel is relatively cold and low in conductivity (Kong et al., 2008; Saba  
 87 et al., 2008; Warner et al., 2012; Saraiva et al., 2014; Mazur, 2016; Wang et al., 2019;  
 88 Huang et al., 2021; Jiang et al., 2022; Ding et al., 2022).

89 As noted by Jensen et al. (2021), there is a disagreement within the lightning com-  
 90 munity about the proper terminology for the K-leader phenomenon. In Kitagawa (1957)  
 91 where the term K-change was coined, the step-like field changes were attributed to pro-  
 92 cesses similar to both recoil streamers and dart leaders. The leader associated with a K-  
 93 change was later called a K streamer/leader (Shao et al., 1995; Stock et al., 2014). All  
 94 three terms (dart leader, K-leader, recoil streamer/leader) and minor variations on them  
 95 continue to be used today in the community (Winn et al., 2011; Stock et al., 2014; Akita  
 96 et al., 2010; Hare et al., 2021) despite their generally recognized equivalence (Kitagawa,  
 97 1957; Shao et al., 1995; Mazur, 2002; Stock et al., 2014; Mazur, 2016). A more complete  
 98 discussion of the terminology and its history can be found in Rakov and Uman (2003)  
 99 sections 4.10 and 9.5, Zhu et al. (2014), and Stolzenburg et al. (2015) section 6. In this  
 100 paper we will exclusively use the term “K-leader” to refer to this phenomenon.

## 101 2 The BIMAP-3D System

102 We have recently introduced the Broadband Interferometric Mapping And Polariza-  
 103 tion in 3D (BIMAP-3D) system at Los Alamos National Laboratory (LANL). BIMAP-  
 104 3D consists of two stations separated by 11.5 km. Each station consists of four dual-polarization  
 105 VHF antennas (20-80 MHz), which are combined to provide 2D source location and po-  
 106 larization measurements. Results from the two stations are combined to give 3D loca-  
 107 tion and polarization measurements. In this paper we will focus on the 3D location re-  
 108 sults. In a favorable scenario when a lightning flash occurs at high altitude between the  
 109 two stations K-leader channels can be mapped with a resolution of 10 m or better in the  
 110 three coordinate directions (easting, northing, and altitude) (Shao et al., 2023). Each  
 111 BIMAP-3D station also has a fast electric field change sensor, or fast antenna.

**Figure 1.** Overview of the presented flash, showing altitude (relative to sea level) vs time (a), northing vs easting (b), altitude vs easting (c), and altitude vs northing (d). The origin (zero) of the Easting/Northing coordinate system is defined as the position of the center antenna of the BIMAP1 station, while a white dot marks the flash origin point in panels b, c, and d. The K-leaders in the later part of the flash are boxed in panel a, and a region in panel b is marked with a dashed outline for closer inspection later in Section 6.

The K-leaders presented in this paper occurred in a hybrid intra-cloud/cloud-to-ground (IC/CG) bolt-from-the-blue flash, and the flash's overall structure and development were reported earlier by Shao et al. (2023), as shown in Figure 1. Animation 1 in the supplementary material also provides an overview of the full flash development (Jensen et al., 2023). The flash begins as a typical IC, with the negative stepped leader growing upward. After about 20 ms scattered sources descend to around 8 km altitude (Figure 1a). Beginning at 50 ms, one of the negative leader branches grows from the origin to the southwest and eventually reaches the ground at about 180 ms, at a horizontal distance of 5.5 km from the flash origin. As the return stroke travels back up, it produces VHF sources at the tips of many earlier channels and branches, indicating that it attempts to neutralize previously deposited charge along these channels and branches. In addition, some new, fast-propagating, and positive breakdown branches were produced by the return strokes, e.g., the lime green branches in the region of 1 and 2 km easting and -6.5 and -8 km northing in Figure 1, similar to that reported in Shao et al. (1995).

130

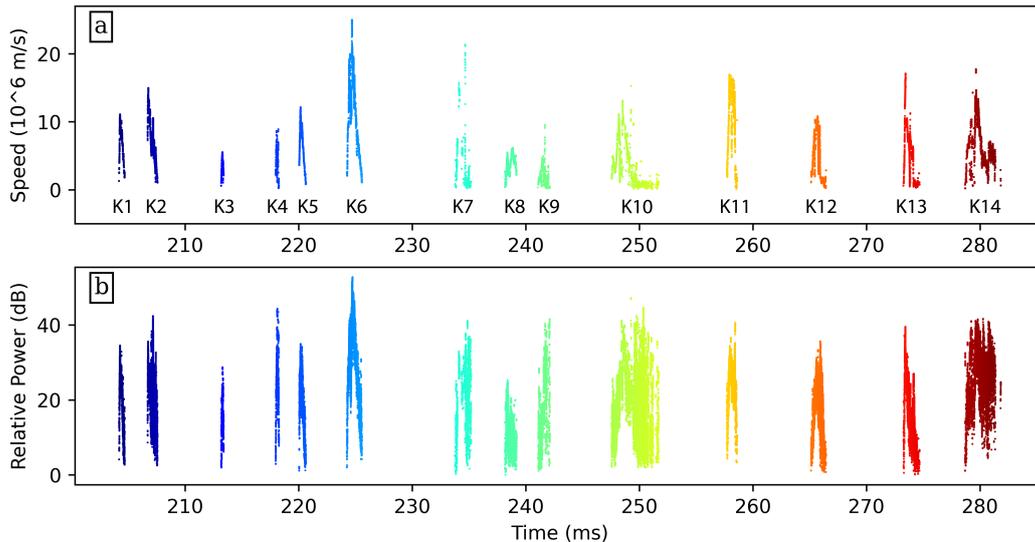

131

132

133

134

The data gap between 190 ms and 205 ms is due to a lack of trigger in our instrumentation, suggesting any activity during this period was relatively quiet in VHF. After 200 ms nearly continuous activity extends the positive discharge region to the northeast while descending from 7.5 km to 6.5 km altitude. This gradual descent is periodically interrupted by 14 K-leaders which each rapidly retrace part of the existing channel structure. Most of the observed K-leaders occurred high above the ground in the cloud as normal intra-cloud K-leaders. The last K-leader in the data record propagated near to the ground along the initial leader channel but stopped at 2 km above the ground.

**Figure 2.** Plot of speed vs time (a) and VHF power vs time (b) for all the K-leaders from the analyzed flash. The K-leaders are labeled K1 through K14.

135 In this paper, we will investigate the K-leader and the inter-K-leader activities, marked  
 136 with a box in Figure 1a. Animation 2 in the supplementary materials provides a clear  
 137 view of the 3D development in this later portion of the flash (Jensen et al., 2023).

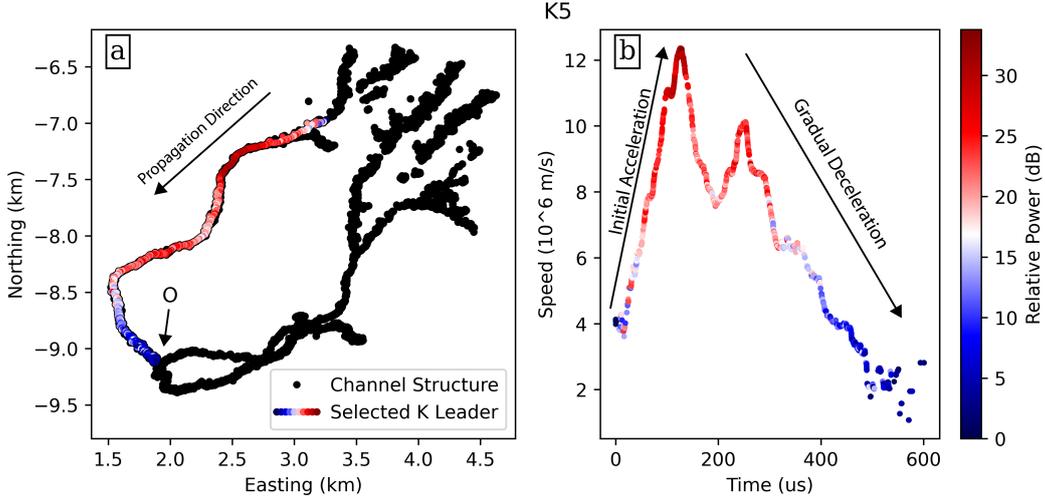

## 138 4 K-leader VHF Power and Propagation Speed

### 139 4.1 Overview of All K-leaders

140 Since we have not thoroughly calibrated our VHF antennas and the specific BIMAP  
 141 receivers, we will not present VHF power in an absolute scale in this study. Instead, a  
 142 relative measure of signal to noise ratio (SNR) will be used (Shao et al., 2020). In this  
 143 case the “noise” level is determined by the lowest received power level among all the an-  
 144 alyzed K leaders. SNR for each located source is referenced to this noise level, and is ad-  
 145 justed by the distance from the source to the antennas. Since the results presented only  
 146 concern trends of increasing and decreasing VHF power the lack of absolute calibration  
 147 should not affect the validity of our conclusions.

148 To estimate K-leader propagation speed, a linear fit of the source position vs. time  
 149 was taken in the three coordinate directions ( $x, y, z$ ) respectively, giving a velocity vec-  
 150 tor ( $V_x, V_y, V_z$ ). The leader propagation speed is computed from the corresponding ve-  
 151 locity vector. The linear fits were calculated in time windows of  $\pm 15 \mu\text{s}$  centered on each  
 152 source. In order to exclude errors in the velocity calculation caused by sources from mul-  
 153 tiple simultaneous branches, we restricted sources to be within 500 m of each centered  
 154 source. Under conservative estimates, the one sigma uncertainty in the speed calcula-  
 155 tions is  $10^5 \text{ m/s}$ , at least an order of magnitude lower than all of the measured K-leader  
 156 speeds, and is sufficiently low for this study. Appendix A provides full detail on how the  
 157 speed uncertainty was calculated.

158 Figure 2a shows an overview of the speed and power vs time for all the K-leaders,  
 159 and labels them K1 through K14. The path of each K-leader is shown in Animation 2  
 160 in the supplementary materials (Jensen et al., 2023). As illustrated in Figure 2a, the K-  
 161 leaders typically start and end at a lower speed, reaching a higher speed somewhere in

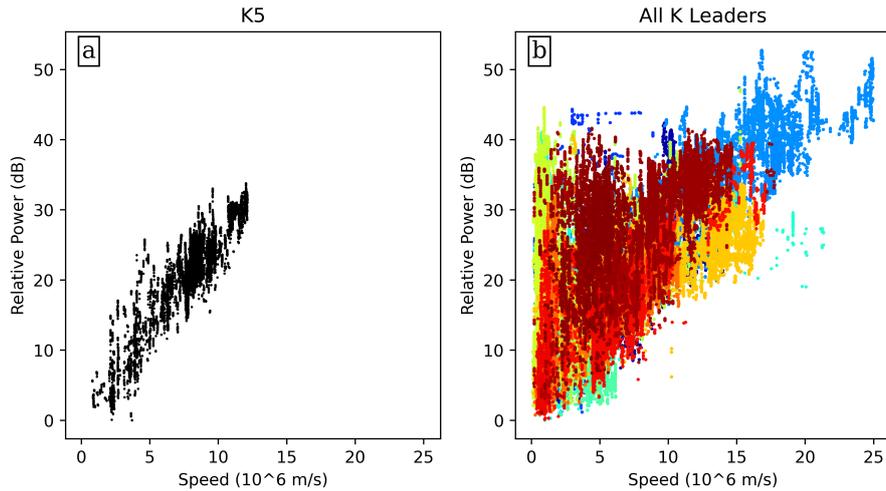

**Figure 3.** Plot of the path of the fifth K-leader (K5) with the background channel structure in Northing vs Easting (a), and the speed of K5 vs time (b). The K-leader sources in both panels are colored by relative VHF power. The flash origin is marked O, along with an arrow for the general propagation direction from the outer branches towards the origin. The first order trends of initial acceleration and gradual deceleration are also marked in panel b.

162 the middle of their propagation, sometimes with significant variations throughout. A sim-  
 163 ilar speed trend was reported by Jensen et al. (2021), although two of the leaders in that  
 164 study apparently started near their maximum speed. The K-leaders analyzed by Hare  
 165 et al. (2023) also generally follow these speed trends, although it is clear that individ-  
 166 ual K-leaders may deviate from the trends for part or all of their development.

167 Figure 2b shows relative VHF power vs time for these K-leaders. The same gen-  
 168 eral trend as that of the propagation speed is observed. They commonly start and end  
 169 with lower power levels and reach a higher power level in the middle of their develop-  
 170 ment, apparently correlated with the speed of K-leader propagation. In a few cases the  
 171 VHF power stayed high while the propagation speed has dropped down toward the end  
 172 of the propagation, as seen for K10 and K14. These cases apparently correspond to a  
 173 transition from a normal K-leader propagation to a more step-like propagation mode.  
 174 This seems to be fairly common at the end of a K-leader’s development, K7, K12, and  
 175 K13 show similar behavior for their last 500  $\mu$ s or so with an average propagation speed  
 176 of around  $1 \times 10^6$  m/s. Apparent stepping propagation can be seen in more detail in  
 177 the supplementary figures (Jensen et al., 2023).

## 178 4.2 Detailed Analysis of a Well Defined K-leader

179 We now examine the fifth K-leader (K5 in Figure 2) for detailed analysis. K5 prop-  
 180 agates along a single branch and has a relatively simple speed behavior. Figure 3a shows  
 181 the path of K5, extending about 3 km, with points colored by VHF power. In this plot  
 182 the black dots show the background channel structure for this part of the flash. Figure  
 183 3b shows the speed vs. time of K5, again colored by VHF power. This simple K-leader  
 184 clearly shows a strong initial acceleration from  $4 \times 10^6$  m/s to its maximum speed of  
 185  $12 \times 10^6$  m/s in the first 150  $\mu$ s. It then gradually decelerates to  $2 \times 10^6$  m/s over the  
 186 remaining 450  $\mu$ s, until the K-leader sources cease altogether. During the deceleration  
 187 there is a temporary re-acceleration from 200  $\mu$ s to 250  $\mu$ s. Speed variations like this are  
 188 common and in some cases may overwhelm the typical acceleration or deceleration of

**Figure 4.** Plot of relative power vs speed for K5 (a), and and for all K-leaders, colored by time (b).

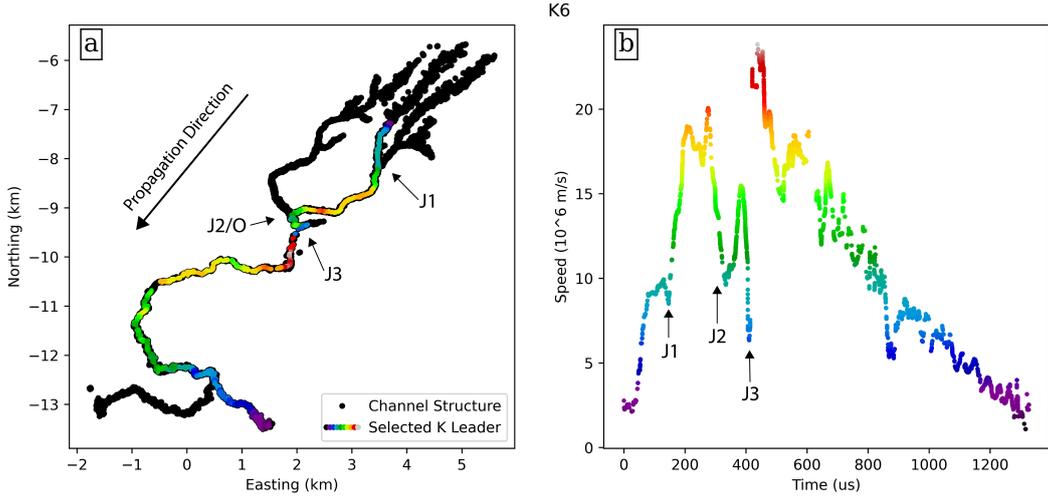

189 the K-leader. Since the general dynamics of K-leaders are still not well understood we  
 190 will focus on first order trends and leave other variations to future investigations. In gen-  
 191 eral the way the speed of this K-leader changes over time is similar to those reported by  
 192 Jensen et al. (2021) and Hare et al. (2023).

193 Figure 3b shows a strong correlation between the leader’s speed and power, with  
 194 the source power starting low, increasing to near its maximum at  $150 \mu\text{s}$ , and then drop-  
 195 ping back down to the lowest power level toward the end of the K-leader. The relative  
 196 power level for this K-leader changed from 0 to about 30 dB across its development.

197 Figure 4a shows the relative VHF power vs propagation speed for K5. The appar-  
 198 ent linear relation between the propagation speed and the logarithmic power indicates  
 199 an exponential relationship between the two parameters. These results are similar to those  
 200 recently reported by Hare et al. (2023). Figure 4b is similar to Figure 4a but for all K-  
 201 leaders in the flash (Figure 2). At low speed there seems to be a wide range of VHF source  
 202 powers. However, much of this apparent scatter is due to the transition from smoother  
 203 K-leader propagation to a more step-like propagation as noted for K10, K14, and sev-  
 204 eral others. The correlation between VHF power and speed is still readily apparent at  
 205 higher speeds for all 14 K-leaders. Apparently in the step-like propagation mode K-leaders  
 206 can emit significantly higher VHF power than a more smoothly propagating K-leader  
 207 at the same speed.

### 208 4.3 Effect of Branch Junctions on K-leader Speed

209 In the previous example we examined a K-leader propagating along a single branch.  
 210 Figure 5 on the other hand shows the 6th K-leader (K6, Figure 2), which passes two branch  
 211 junctions, or intersections. We now examine whether branch junctions affect the K-leader  
 212 propagation speed. The black dots in Figure 5a now show the full background channel  
 213 structure for the flash, whereas in Figure 3 only the northern portion of the channel struc-  
 214 ture was shown. The upper branch (extending from J3, Figure 5a) has been truncated  
 215 to avoid the false appearance of junctions. This truncated branch is at higher altitude  
 216 than the other branches but overlays them in easting and northing (Figures 1c and 1d).  
 217 The K-leader path in Figure 5a and the points in Figure 5b are colored by speed.

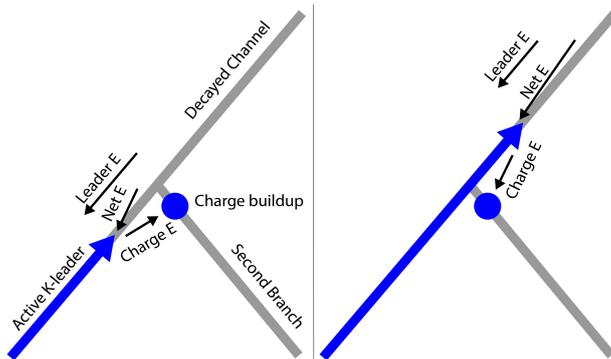

**Figure 5.** A plot of the path of the 6th K-leader (K6) relative to the overall branching structure in Easting vs Northing (a), and the speed of K6 vs time (b), with the K-leader points colored by speed. The junctions J1, J2, and J3, are marked in both panels. J2 is also at the flash origin, marked O. The general propagation direction is indicated with an arrow, K6 begins in the north and ends in the south end of the plot.

218 K6 starts with a rapid initial acceleration from  $1.5 \times 10^6$  m/s up to  $9 \times 10^6$  m/s,  
 219 and then reaches a speed plateau around  $100 \mu\text{s}$ . This occurs as the K-leader approaches  
 220 the first junction (J1). After passing J1 the K-leader rapidly accelerates again up to  $20 \times$   
 221  $10^6$  m/s. The K-leader then decelerates to  $10 \times 10^6$  m/s as it approaches the second junc-  
 222 tion at the flash origin (J2/O) around  $320 \mu\text{s}$ . After passing J2 the K-leader accelerates  
 223 to  $15 \times 10^6$  m/s at  $385 \mu\text{s}$ , before decelerating to  $6 \times 10^6$  m/s as it approaches the third  
 224 junction (J3) at  $410 \mu\text{s}$ . The K-leader then rapidly reaches its maximum speed of  $25 \times$   
 225  $10^6$  m/s at  $430 \mu\text{s}$ , before gradually decelerating to  $2 \times 10^6$  m/s at  $1300 \mu\text{s}$ . Variations  
 226 occur within the gradual deceleration, but investigations into the nature of these vari-  
 227 ations will be left to future research.

228 The pattern observed is that when the K-leader approaches a branch junction it  
 229 decelerates, and after it passes a junction it accelerates. Similar behavior has been ob-  
 230 served for many other K-leaders in this flash, figures for these K-leaders are included in  
 231 the supplementary material (Jensen et al., 2023). These common propagation behaviors  
 232 are an interesting observation and can be explained as the following (Figure 6). When  
 233 the branches are inactive prior to the K-leader, the channels are apparently poorly con-  
 234 ductive. Due to previous discharge activity more negative charge is expected be deposited  
 235 along the channels towards the direction of the flash origin, or toward the branch junc-  
 236 tion points. When the active K-leader approaches the junction the electric field at the  
 237 leader tip will be decreased by the previously deposited negative charge from the other  
 238 branch, and this will slow down the active K-leader. Once the K-leader passes the junc-  
 239 tion the deposited charge along the inactive channel will on the other hand increase the  
 240 field at the leader tip, leading to re-acceleration of the K-leader. Additionally, when the  
 241 K-leader passes the junction it is possible that the other inactive channel becomes more  
 242 conductive, and this will further enhance the field at the passing K-leader tip and help  
 243 to speed up the propagation.

244 This interpretation of the deceleration when a K-leader approaches a junction is  
 245 further supported by K1, K3, and K5, which all stop at the first junction they meet. K1

**Figure 6.** A simple diagram showing the hypothesized interaction of a K-leader with charge deposits left behind near branch junctions. As the K-leader approaches the junction the fields from the leader tip and deposited charge destructively interfere. As the K-leader passes the junction the fields change to constructively interfere.

246 and K3 can be seen in Animation 2 and their corresponding figures in the supplement-  
 247 ary material (Jensen et al., 2023). As reported previously in 2D interferometer obser-  
 248 vations (Shao & Krehbiel, 1996) and more recently in 3D observations (Shao et al., 2023),  
 249 shorter K-leaders often stopped at a branch junction, indicating that sufficient negative  
 250 charge was deposited near or at the junction points to reduce the electric field below the  
 251 breakdown threshold at the leader tip.

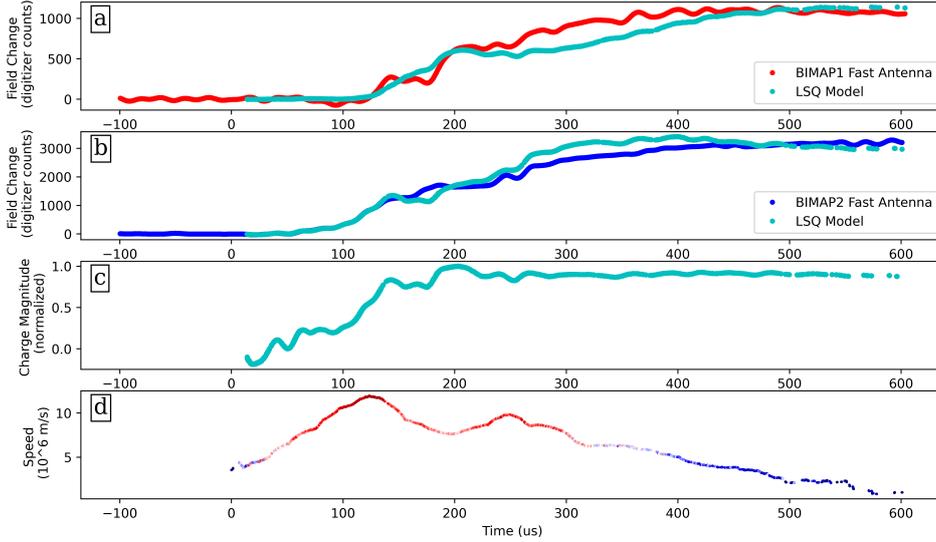

252 In addition to the branch junction effect, other minor speed variations are observed  
 253 throughout the K-leader development. We cannot point to a single factor that may cause  
 254 these variations. We leave analysis of these variations to future investigations.

## 255 5 K-leader Electric Field Change

256 Two fast antennas are deployed with the BIMAP-3D system, one at each station.  
 257 The two fast antennas have different effective gains due to the deployment setup. A rel-  
 258 ative calibration was achieved between the two fast antennas by comparing the magni-  
 259 tude of field changes for distant flashes (around 50 km from each station). Based on this  
 260 comparison the fast antenna at BIMAP2 is more sensitive than that at BIMAP1 by a  
 261 factor of 2, with an estimated uncertainty of 10%.

262 The amplifiers in the fast antennas also had different time constants (0.2 ms and  
 263 1 ms), and the recorded field changes were “de-drooped” accordingly (Sonnenfeld et al.,  
 264 2006; Födisch et al., 2016). The field change for each K-leader was de-drooped separately  
 265 and the average field for a time period of 100  $\mu$ s before each K-leader was set to zero.  
 266 The fast antenna signals were lowpassed at 50 kHz to focus on the electrostatic field com-  
 267 ponent.

268 Using the recorded field changes from both stations, we modeled the electric field  
 269 as being produced by a point charge at the leader tip. An opposite point charge was placed  
 270 at the origin of the K-leader for charge conservation. This charge arrangement is a greatly  
 271 simplified approximation of the charge distribution expected for an equipotential K-leader  
 272 channel (Kasemir, 1960; Mazur & Ruhnke, 1998). The ground is assumed to behave like  
 273 an infinite conducting plane. Then for a sensor located at a point  $(X, Y, Z)$ , where  $Z$  is  
 274 the ground altitude at the station, the vertical electric field due to the two point charges  
 275 at a given time is given by

**Figure 7.** Plot of electric field change for K5 at BIMAP1 vs time (a), showing both the measured field change (red) and modeled field change (turquoise). Electric field change at BIMAP2 vs time (b), showing both the measured field change (blue) and modeled field change (turquoise). Modeled charge magnitude vs time (c), and speed vs time (d), colored by power.

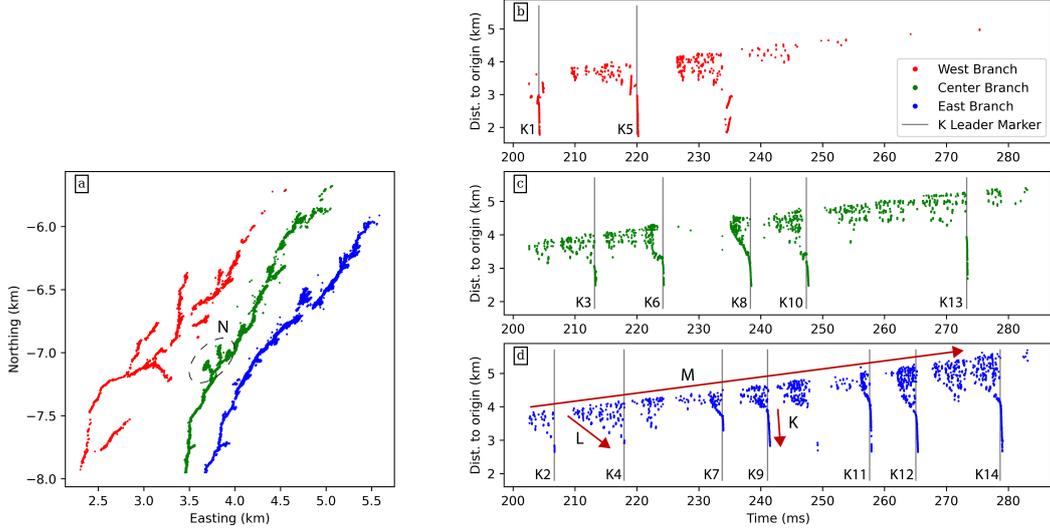

$$E = \frac{-Q}{2\pi\epsilon_0} \left( \frac{z_1 - Z}{(x_1 - X)^2 + (y_1 - Y)^2 + (z_1 - Z)^2} - \frac{z_0 - Z}{(x_0 - X)^2 + (y_0 - Y)^2 + (z_0 - Z)^2} \right) \quad (1)$$

276 where  $(x_1, y_1, z_1)$  stands for the K-leader tip,  $(x_0, y_0, z_0)$  stands for the K-leader  
 277 origin, and  $Q$  is the charge at the two points.

278 The magnitude of the charge  $Q$  in Equation 1 at a given time was estimated using  
 279 a weighted least-squares fit between the two recorded field changes, accounting for  
 280 the speed-of-light time delay between the leader tip and the respective fast antennas. The  
 281 weighting was based on the total change of the field for the entire K-leader recorded by  
 282 each fast antenna to avoid over-fitting to the closer antenna.

283 Figure 7 shows the modeled field at each station compared to the measured field  
 284 (panels a and b) for K5, along with the variation in the modeled charge over time (panel  
 285 c). The velocity and power over time are also included in the bottom panel (d) for com-  
 286 parison. As shown in Figure 7, the point charge model is a good first order fit to the mea-  
 287 sured field changes at both stations for K5. The modeled charge increases initially and  
 288 then stays relatively constant for the rest of the K-leader duration. It is also observed  
 289 that the increase in charge is generally correlated with the initial propagation accelera-  
 290 tion and VHF power increase at the beginning of the K-leader.

291 It is important to note that this level of fit was only achieved for two of the K-leaders  
 292 from this flash. Figure 7 shows the fit for K5, which propagated along a single branch  
 293 (Figure 3). Similar results were observed for K1 (Figure 2), which travels along the same  
 294 branch. K3 also developed along a single branch and showed similar charge behavior,  
 295 but the quality of the fit to the measured fields changes was worse. This is possibly be-  
 296 cause the field change for K3 was small, and thus more dominated by local noise. The  
 297 other K-leaders all pass multiple branch junctions (Figure 5, and supplementary figures

**Figure 8.** Northing vs. Easting plot of three manually separated branches of the positive leader (a), with plots of the distance from the flash origin vs. time for the west (b, red), center (c, green), and east (d, blue) branches. Gray vertical lines on the distance vs. time plots indicate that a K-leader began on that branch at that time. The K-leaders are labeled K1 through K14 chronologically.

298 (Jensen et al., 2023)), and cannot be fit with the simple two point charge model. In these  
 299 cases the K-leader may redistribute charge along multiple branches as it passes a junc-  
 300 tion. Even in the single branch case our two point model may be too simplified to ac-  
 301 curately capture the evolution of the charge distribution on the channel, but this is one  
 302 of the first attempts to explore this behavior.

## 303 6 VHF Sources Between K-leaders

304 Figure 8 shows the activity that occurs in the positive discharge region after the  
 305 return stroke. Figure 8a is a Northing vs. Easting plot of the three main branches, which  
 306 have been grouped into three separate data sets so that they can be analyzed individ-  
 307 ually. The region containing these branches is marked out with a dashed border in Fig-  
 308 ure 1b. The region in Figure 8 has been chosen to include essentially all sources in the  
 309 positive breakdown region, while excluding the K-leaders themselves as much as possi-  
 310 ble. The full development of this region, along with the K-leaders initiating from it, can  
 311 be seen in Animation 2 in the supplementary material (Jensen et al., 2023).

312 Figures 8b, c, and d show the distance from the sources to the flash origin vs time  
 313 for the west (red), center (green), and east (blue) branches respectively. The time at which  
 314 a K-leader is launched on a particular branch is marked with a gray vertical line. In most  
 315 cases K-leader sources are shown as a nearly vertical cluster that coincides with the gray  
 316 vertical markers. In some cases, the K-leader initiates just outside of the analyzed re-  
 317 gion and thus the sources do not appear in Figure 8.

318 Figure 8 shows three interesting insights into K-leader initiation and development.  
 319 First, in every case the launch of a K-leader (at the times of the gray lines) is followed  
 320 by an RF quiet period (typically 1-2 ms but sometimes exceeding 10 ms). The VHF sup-  
 321 pression occurs specifically on the branch that launched the K-leader. Other branches  
 322 may continue to emit VHF, or may also be suppressed. For example, the VHF suppres-

323 sion on the center channel (green, Figure 8c) after K3 does not occur on the other two  
 324 branches (blue and red). On the other hand, K6 on the center branch (green, panel c)  
 325 does seem to also suppress the east branch (blue, panel d). Hare et al. (2021) reported  
 326 similar VHF suppression and referred to it as the K-leader “quenching” the activity on  
 327 the channel.

328 Secondly, there appear to be three different types of processes that proceed at three  
 329 different characteristic speeds. Examples of the three processes are labeled with arrows  
 330 as K, L, and M in Figure 8d. The best understood, and fastest, of these are the K-leaders  
 331 themselves, labeled K, typically initiating at speeds on the order of  $10^6$  m/s. The inter-  
 332 mediate speed process, labeled L, is suggested by the downward slope at the bottom of  
 333 each group of sources, and seems to extend at speeds on the order of  $10^5$  m/s. The slow-  
 334 est process is the gentle upward source extension, labeled M, at speeds on the order of  
 335  $10^4$  m/s. These three processes will be discussed further in Section 7.3.

336 Finally, it appears that the possible launch of a K-leader along one branch is some-  
 337 times stopped by the initiation of a K-leader on a different branch. For instance the fea-  
 338 tures of the scattered sources after K9 (between 243 ms and 248 ms) along the blue branch  
 339 (Figure 8d) suggest a K-leader could soon be initiated, but instead K10 along the green  
 340 branch occurs at this time. K10 apparently suppresses the scattered sources on both branches  
 341 and appears to stop a K-leader from initiating on the blue branch. Similarly, K6 (green)  
 342 appears to stop a K-leader on the blue branch. K11 and K12 (blue) also appear to stop  
 343 K-leaders on the green branch. These observations indicate that neighboring branches  
 344 can affect each other through the K-leader process.

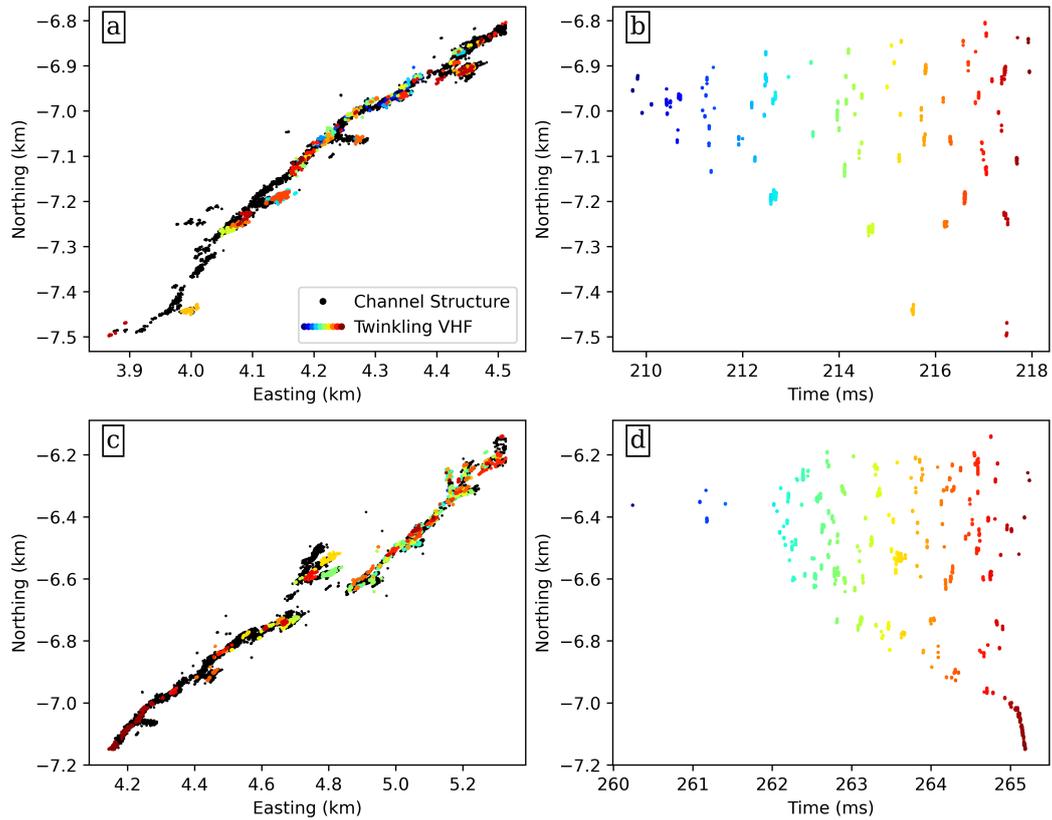

## 345 7 Discussion

### 346 7.1 On Needles and “Twinkling”

347 We note that there are some small side-branches on the channels in Figure 8a, two  
 348 examples on the center channel have been circled and labeled N. These small branches  
 349 are the recently identified needles (Hare et al., 2019; 2021; Pu & Cummer, 2019). Saba  
 350 et al. (2020) showed high speed video evidence of needles forming as failed branching at-  
 351 tempts on upward positive leaders. Saba et al.’s suggested mechanism for needle forma-  
 352 tion is especially convincing because it explains why needles are typically inclined in the  
 353 forward direction of the positive leader. In this study essentially all the protrusions from  
 354 the channels are at  $45^\circ$  or less with the main channel (Figures 8a, 9a, and 9c). This is  
 355 opposite to the orientation that would be expected if needles were formed originally by  
 356 the negative end of a cut-off channel as proposed by Hare et al. (2019). The corona-field-  
 357 reversal mechanism proposed by Pu and Cummer (2019) suggests that needles should  
 358 be mostly orthogonal to the channel or uniformly distributed around  $90^\circ$ , which is also  
 359 not consistent with our observations.

360 Regarding the VHF “flickering”, Stock et al. (2014) reported that positive lead-  
 361 ers flickered in a somewhat random way, and Hare et al. (2019) reported that most of  
 362 these flickering, or “twinkling”, sources are associated with needles. While the claim in  
 363 Hare et al. (2019) appears to be true for the flash they analyzed, it is not clear that it  
 364 is true in general. Hare et al. (2019) (their Figure 2) still shows a few twinkling sources  
 365 that occur along the main channel but not clearly on needles, and the same is true for  
 366 Hare et al. (2021) (their Figures 20 and 21). Pu and Cummer (2019) also showed many  
 367 twinkling sources that are arguably on the main positive channel rather than on any needle  
 368 (their Figure 2).

369 Our results in this study are shown in Figure 9, for two time intervals (top and bot-  
 370 tom) between K-leaders. The left-hand panels (a and c) show the channel structure and  
 371 location of the twinkling sources in northing vs. easting, where the background chan-  
 372 nel structure consists of all VHF sources in that region throughout the flash. The right-

**Figure 9.** Two examples of twinkling behavior between K-leaders. The top panels show the location of twinkling sources and the background channel structure in Northing vs. Easting (a) and twinkling in Northing vs. time (b) for the period between K2 and K4, while the bottom panels show Northing vs. Easting (c), and Northing vs. time (d) for the period between K11 and K12. Both selections are on the east branch of Figure 8. The twinkling sources are colored by time.

373 hand panels (b and d) show the twinkling sources in northing vs. time. In the bottom  
 374 half of Figure 9a the twinkling sources seem to appear preferentially on the needles. The  
 375 rest of the twinkling sources in Figures 9a and c seem to appear equally on needles and  
 376 the main channel. The occurrence frequency of twinkles in Figures 9b and d also appears  
 377 to be the same between sources on needles and on the channel.

378 We cannot rule out the presence of needles smaller than our spatial resolution, but  
 379 in some areas in Figures 9a, and c twinkling sources seem to densely fill the channel. This  
 380 does not seem consistent with sources occurring on distinct needle branches. Since their  
 381 appearance in space and time is essentially the same, we consider all of the sources in  
 382 Figures 8 and 9 to be VHF twinkling, except those associated with K-leaders. Other than  
 383 appearing more commonly along the main channel our VHF twinkling observations are  
 384 broadly in agreement with previous reports (Hare et al., 2019;2021; Pu & Cummer, 2019),  
 385 although the individual twinkling events are too short in space and time for us to resolve  
 386 their development.

387 Regarding the needle structures, our observations of needle orientation relative to  
 388 the main channel, and high speed video observations of needle formation (Saba et al.,  
 389 2020), indicate that ionized structures are already present prior to the detection of VHF-  
 390 visible needles, and the needles sources simply occur on the pre-existing structures. The  
 391 pre-ionized needle structures are apparently due to failed branching attempts of the VHF  
 392 quiet positive leader tip. The observations of Hare et al. (2021) that subsequent twin-  
 393 kles on the same needle in general do not extend the needle length is consistent with our  
 394 interpretation. Based on our observations VHF twinkling is associated with both the nee-  
 395 dles (failed positive branches) and the main body of the positive channel, which are both  
 396 part of the pre-ionized channel structure.

397 As an interesting observation, Figure 9b indicates that the twinkling rate is higher  
 398 closer to the positive tip (further north in this case), and the distance between twinkling  
 399 sources also seems to be smaller towards the tip. The fact that the same behaviors are  
 400 more clear in Figure 9b than Figure 9d may be due to the fact that the majority of the  
 401 twinkling sources appear within just 2.5 ms in Figure 9d, vs 10 ms in Figure 9b. Pu and  
 402 Cummer (2019) also reported that the spatial and temporal density of twinkles was high-  
 403 est near the forward tip.

404 As shown earlier in Figure 8, the downward slope of the southern edge of the twin-  
 405 kling region, and the gentle average upward slope of the northern edge, are both appar-  
 406 ent in Figure 9 panels b and d. Our interpretation of these upward and downward slopes  
 407 will be discussed in Section 7.3.

## 408 7.2 Quenching vs Masking

409 With LMA observations of a triggered upward positive leader, Edens et al. (2012)  
 410 reported that temporal gaps in the positive leader sources seemed to correspond to si-  
 411 multaneous lower altitude negative breakdown. They attributed this to the masking of  
 412 higher power negative sources over the weaker positive sources. Although this masking  
 413 could play a role in suppressing VHF sources on the positive leader, K3 in this study (green,  
 414 Figure 8c) does not interrupt the twinkling on the other two branches (red and blue).  
 415 There are multiple examples in this flash where a K-leader occurs with simultaneous on-  
 416 going VHF twinkling on the other branches. For instance, this occurs for K1 and K5 on  
 417 the red branch, K8 and K13 on the green branch, and K9 on the blue branch.

418 We can thus infer that the quenching of VHF sources is a real effect, presumably  
 419 caused by a change in the physical state of the channel during and after a K-leader. The  
 420 fact that after quenching the twinkling sources re-start near the apparent positive tip  
 421 before extending back towards the origin also points to a physical change in the chan-  
 422 nel conditions.

High speed video observations show K-leaders significantly increasing the channel luminosity (Kong et al., 2008; Saba et al., 2008; Warner et al., 2012; Mazur, 2016; Wang et al., 2019; Huang et al., 2021; Jiang et al., 2022; Ding et al., 2022), indicating increased temperature and conductivity along the channel at that time. Since this is coincident with the suppression of VHF twinkling in this study, we can infer that the increased conductivity is the reason for the VHF quenching. In the cases where a K-leader quenches multiple channels, there must be a conductive connection between those branches. For instance, after K10 on the green branch (Figure 8c) the twinkling along the blue branch (panel d) is also suppressed. Such an inter-connection is consistent with our discussion of K-leaders displacing charge along multiple branches in Section 5, and with our suggestion that a K-leader can interrupt the initiation of other K-leaders (Section 6).

The duration of VHF quenching should therefore be related to the decay time for a conductive K-leader channel to become non-conductive. Shao et al. (2012) predicted that the decay time for a dart leader channel can be approximated as  $\tau = 0.17e^{z/2.3}$  (ms), where  $z$  is altitude in km. At 6 km where the K-leaders started in this study, the decay time would be 2.3 ms. This is surprisingly close to the typical quenching duration observed in Figure 8.

If quenching is caused by the increased conductivity of the K-leader channel, the masking observed by Edens et al. (2012) may have been caused by the same effect. Their observations are generally consistent with the upward positive leader branches producing downward K-leaders, and in some cases these K-leaders may have quenched all the positive leader branches. On the other hand the LMA is probably more susceptible to masking because of its longer integration windows compared to BIMAP-3D (10  $\mu$ s-100  $\mu$ s compared to  $\sim 0.5$   $\mu$ s).

### 7.3 Three Characteristic Speeds in the Positive Breakdown Region

Among the three characteristic speeds in Figure 8, the fastest is the K-leader itself starting on the order of  $10^6$  m/s (labeled K), which consists of negative breakdown and is clearly visualized by BIMAP-3D. The slowest process on the order of  $10^4$  m/s (labeled M) is associated with the extension of the positive leaders. Since we generally do not see the positive leader tip itself in VHF (Pu et al., 2021; Stock et al., 2023) it is not surprising that this extension seems to continue whether VHF is observed or not. This is most obvious in Figure 8b where very few VHF sources were detected after 250 ms but the upward slope is still apparent. Even though the observed VHF sources are probably not at the positive leader tips, it is reasonable to assume that the true positive leader tip is at a roughly fixed distance ahead. In Figure 8, the average extension speed of all three branches is the same,  $2 \times 10^4$  m/s. It is interesting to note that the occurrence of K-leaders does not appear to have any significant effect on this extension speed.

The intermediate speed process on the order of  $10^5$  m/s (Figure 8d, labeled L) is difficult to interpret. A more detailed view of this development is shown in Figures 9b and d. This speed is associated with the extension of the VHF twinkling region towards the direction of the flash origin, but not related to any well defined channel propagation. Although this extension leads to the start of the next K-leader, with our current observations we do not understand the physical mechanism for this process. Nevertheless this process is clearly associated with K-leader initiation because the downward development in Figures 8c and d generally continues until either a K-leader is initiated or the process is interrupted by a K-leader from another channel.

Optical observations by other researchers show that the channel is dark before a K-leader initiates (Kong et al., 2008; Mazur, 2016; Wang et al., 2019; Huang et al., 2021; Jiang et al., 2022; Ding et al., 2022). In Section 7.2 we argued that VHF twinkling was suppressed on a conductive channel. Taking these together it suggest that the process

473 that causes VHF twinkling and that initiates K-leaders should occur on relatively cold/low  
474 conductivity channels.

475 Hare et al. (2021) and Pu and Cummer (2019) both reported on the forward ex-  
476 tension of the twinkling region along a channel with similar distance vs time plots to our  
477 Figure 8 (their Figures 22 and 4 respectively). Pu and Cummer (2019) estimated a 2D  
478 average speed of  $1 \times 10^5$  m/s for this forward progression, Hare et al. (2021) reports  $5 \times$   
479  $10^4$  m/s for their case, both are higher than our estimated speed of  $2 \times 10^4$  m/s. In ad-  
480 dition, they did not observe the intermediate speed process progressing towards the di-  
481 rection of the flash origin, nor did they report any K-leaders during this interval. In our  
482 study the progression towards the flash origin seems to be a feature of twinkling specifi-  
483 cally at the stage when K-leaders are being actively produced.

484 All the VHF twinkling in Figures 8 and 9 is probably the same process we identi-  
485 fied as “blooming” in Jensen et al. (2021). The spatial and temporal resolution in Jensen  
486 et al. (2021) was insufficient to identify the extension forward and expansion back to-  
487 ward the flash origin, or to make the association with reported observations of VHF twin-  
488 kling on needles.

#### 489 7.4 Slow Positive Leaders May Generally be Dim

490 Figures 8 and 9 show scattered VHF twinkling sources in the positive discharge re-  
491 gion, and in Section 7.3 we argued that this takes place on a dark channel. Similar VHF  
492 twinkling on the positive leader is observed in the early part of the flash, starting 20 ms  
493 into the flash (Figure 1a, around 8 km). The similarity in the source scattering and slow  
494 extension ( $\sim 10^4$  m/s) between these two stages of the flash suggests that the positive  
495 leader may also be dim in the early part of the flash. Bright positive leaders have been  
496 observed in high speed video in other studies, but the reported leader speed is typically  
497 one to two orders of magnitude higher ( $10^5$  m/s- $10^6$  m/s) (Saba et al., 2008; Campos  
498 et al., 2014; Kong et al., 2015), suggesting the reported optical positive leaders develop  
499 under different circumstances as compared to the slow in-cloud development as presented  
500 in this paper. Some studies have reported optical observations with evidence of dim or  
501 dark positive leaders extending on the order of  $10^4$  m/s (Kong et al., 2008; Wang et al.,  
502 2019; Jiang et al., 2022).

#### 503 7.5 The Life Cycle of a K-leader

504 Based on the observations presented in this paper, the life-cycle in the simplest case  
505 is as follows: Following a period of VHF twinkling, a K-leader is initiated. The K-leader  
506 then accelerates with increasing charge at both tips, and then the K-leader gradually de-  
507 celerates to a stop with a relatively constant charge at the tips. After a few milliseconds  
508 of VHF quiet period, the twinkling process starts again, and that will lead to the ini-  
509 tiation of the next K-leader. We have already discussed the processes leading to the ini-  
510 tiation of a K-leader in Section 7.3. We now discuss the physical mechanisms that drive  
511 the rest of the K-leader development.

512 Let us first attempt to explain the initial acceleration of the K-leader. The speed  
513 of the K-leader should primarily depend on the electric field strength at the negative leader  
514 tip, and the state of conditioning of the channel to be retraced by the K-leader. Since  
515 the K-leader channel becomes hot once it is started, as observed optically (Kong et al.,  
516 2008; Saba et al., 2008; Warner et al., 2012; Mazur, 2016; Ding et al., 2022), the active  
517 leader section can be treated as conductive and approximately equipotential. For an equipo-  
518 tential channel in a uniform electric field the field strength as well as the charge concen-  
519 tration at the tip would increase linearly with channel length (Kasemir, 1960; Mazur &  
520 Ruhnke, 1998). In this case it is not difficult to understand the leader acceleration as  
521 it propagates forward.

522 However, at the late lightning stage during the K-leader phase the electric field around  
 523 the lightning structures cannot be assumed uniform. Earlier discharges prior to the K-  
 524 leaders have redistributed charge along the channel structures, and the electric field at  
 525 any position would be a superposition of the general background field and the disturbed  
 526 field due to the lightning itself. Nevertheless, at the far extremes of the positive break-  
 527 down region where the K-leaders are initiated, the local field is likely dominated by the  
 528 nearby negative charge concentration in the cloud and is less affected by the main light-  
 529 ning structure. In a small spatial scale in this region, the field can be assumed uniform  
 530 and directed toward the negative charge in the cloud. Under such considerations, the ac-  
 531 celeration along a short section of the leader propagation can be understood.

532 On the other hand, as the K-leader propagates away from the negative cloud charge  
 533 region and toward the main channel structure the lightning-induced charge redistribu-  
 534 tion acts as an increasingly more dominant factor. Since previous discharge processes  
 535 effectively transported negative charge toward the region near and beyond the origin of  
 536 the flash, the field strength at the active leader tip will be continuously reduced as it prop-  
 537 agates toward this region. Under these conditions, the K-leader is expected to slow down  
 538 after its initial acceleration. This also explains why most K-leaders stop at the origin of  
 539 the flash and sometimes at branch junctions, especially for simple IC flashes (e.g., Shao  
 540 and Krehbiel, 1996; Shao et al., 2023). The other factor that helps to slow down the leader  
 541 propagation is the energy dissipation due to the re-ionization of the pre-established but  
 542 cold channel, as discussed in Jensen et al. (2021). However, based on the common devel-  
 543 opment behavior of the K-leaders it appears that the local field plays a dominant role  
 544 on its initial acceleration and later deceleration.

## 545 8 Summary

546 The results in this paper can be briefly summarized as follows:

- 547 1. K-leader propagation speed generally exhibits an initial acceleration followed by  
 548 a gradual deceleration, though the development of individual K-leaders is often  
 549 complex.
- 550 2. K-leader VHF power is exponentially correlated with speed.
- 551 3. Branch junctions affect K-leader speed, and may affect charge redistribution.
- 552 4. In simple cases the K-change can be modeled as time-evolving equal and oppo-  
 553 site charges at the K-leader origin and propagating negative tip.
- 554 5. The estimated charge magnitude at the K-leader tip increases initially, then stays  
 555 relatively constant.
- 556 6. The initial acceleration and charge buildup of K-leaders can be explained by the  
 557 equipotential model.
- 558 7. The gradual deceleration of K-leaders may be due to charge deposited along the  
 559 channel by earlier lightning processes.
- 560 8. VHF twinkling is not unique to needles, it also occurs on the main channel.
- 561 9. We have confirmed that K-leaders quench VHF twinkling, and the quenching is  
 562 a real physical effect, not an observational artifact.
- 563 10. After quenching, the VHF twinkling region extends forward in the positive break-  
 564 down direction at  $\sim 10^4$  m/s, and back towards the origin at  $\sim 10^5$  m/s.
- 565 11. K-leaders are initiated by the extending twinkling process on an optically dark/low  
 566 conductivity channel.
- 567 12. A K-leader from one branch may interrupt progress towards initiation of a K-leader  
 568 on other branches.
- 569 13. Slow positive leaders ( $\sim 10^4$  m/s) may generally be optically dark while they ex-  
 570 hibit VHF twinkling.

571 **Appendix A Speed Uncertainty Analysis**

We can relate the speed uncertainty to the position uncertainty by expressing the speed ( $V$ ) as the difference in time and location of two points

$$V = \sqrt{\left(\frac{x_1 - x_2}{t_1 - t_2}\right)^2 + \left(\frac{y_1 - y_2}{t_1 - t_2}\right)^2 + \left(\frac{z_1 - z_2}{t_1 - t_2}\right)^2} \quad (\text{A1})$$

The uncertainty, expressed as a standard deviation will be of the form

$$\sigma_V = \sum_i \sum_j \left(\frac{\partial V}{\partial i}\right) \left(\frac{\partial V}{\partial j}\right) \sigma_i \sigma_j \quad (\text{A2})$$

572 where the sums for  $i$  and  $j$  are over each variable,  $x_1, x_2, y_1, y_2, z_1, z_2, t_1,$  and  $t_2$ .

The partial derivatives of  $V$  can be summarized as

$$\frac{\partial V}{\partial x_1} = \frac{1}{V} \frac{x_1 - x_2}{(t_1 - t_2)^2} = \frac{V_x}{V \Delta t} \quad (\text{A3})$$

$$\frac{\partial V}{\partial x_2} = -\frac{1}{V} \frac{x_1 - x_2}{(t_1 - t_2)^2} = -\frac{V_x}{V \Delta t} \quad (\text{A4})$$

$$\frac{\partial V}{\partial t_1} = -\frac{1}{V} \frac{(x_1 - x_2)^2 + (y_1 - y_2)^2 + (z_1 - z_2)^2}{(t_1 - t_2)^3} = -\frac{V}{\Delta t} \quad (\text{A5})$$

$$\frac{\partial V}{\partial t_2} = \frac{1}{V} \frac{(x_1 - x_2)^2 + (y_1 - y_2)^2 + (z_1 - z_2)^2}{(t_1 - t_2)^3} = \frac{V}{\Delta t} \quad (\text{A6})$$

573 where  $\Delta t = t_1 - t_2$ ,  $V_x = \frac{x_1 - x_2}{\Delta t}$ , and the equations are symmetric for  $x, y,$  and  $z$ .

574 Computing Equation A2 from the partial derivatives, and assuming the uncertain-  
575 ties are the same for both points (i.e.  $\sigma_{x_1} = \sigma_{x_2}$ , etc.), we can see that most of the terms  
576 will cancel out since half of the partial derivatives are negative and half are positive. Thus  
577 we are left with only the squared terms

$$\sigma_V^2 = \left[ \left(\frac{V_x}{V \Delta t}\right)^2 \sigma_x^2 + \left(\frac{V_y}{V \Delta t}\right)^2 \sigma_y^2 + \left(\frac{V_z}{V \Delta t}\right)^2 \sigma_z^2 + \left(\frac{V}{\Delta t}\right)^2 \sigma_t^2 \right] \quad (\text{A7})$$

If we make a conservative error estimate so that we can assume  $\sigma_x = \sigma_y = \sigma_z = c \sigma_t$ , where  $c$  is the speed of light, then we can combine terms to get

$$\sigma_V^2 = \sigma_x^2 \left[ \frac{1}{\Delta t^2} + \frac{V^2}{c^2 \Delta t^2} \right] \quad (\text{A8})$$

Recognizing that  $\frac{V^2}{c^2} \ll 1$  for any reasonable lightning activity we can drop the second term (associated with  $\sigma_t$ ) and are left with

$$\sigma_V = \frac{\sigma_x}{|\Delta t|} \quad (\text{A9})$$

578 If we further assume that we have  $N$  points and are taking an average of all of the  
579 possible finite differences ( $\frac{1}{2}N(N-1)$  combinations) rather than a single finite differ-  
580 ence then we can apply the central limit theorem and get

$$\sigma_{\bar{V}} = \sqrt{\frac{2}{N(N-1)}} \frac{\sigma_x}{|\Delta \bar{t}|} \quad (\text{A10})$$

581 where  $\sigma_{\bar{V}}$  is the standard deviation of the average speed, and  $\overline{\Delta t}$  is the average time  
582 difference between points.

583 While this averaging method is not identical to the linear fit method used for re-  
 584 sults presented in Figures 2-5, it is tractable to an analytic solution. The linear fit method  
 585 was also evaluated via a Monte Carlo simulation.

586 Parameters for the uncertainty estimation and the resulting uncertainties were de-  
 587 termined as follows: Shao et al. (2023) showed that in an ideal case the random loca-  
 588 tion uncertainty of BIMAP-3D can be better than 10 m in all directions (x, y, and z).  
 589 For the purpose of estimating the speed uncertainty we will use a more conservative es-  
 590 timate of 30 m location uncertainty in all directions for the K-leaders analyzed. If we  
 591 further assume that in a typical 30  $\mu$ s window we have about 30 sources (an underes-  
 592 timate), and the average time difference between sources is about 1/4 the window size,  
 593 then from Equation A10 we get an estimated speed uncertainty of  $2 \times 10^5$  m/s. A Monte  
 594 Carlo simulation was also conducted by repeatedly adding random offsets in each direc-  
 595 tion (Easting, Northing, and altitude) to each source location and then recalculating the  
 596 speeds as compared to the non-offset values. For offsets that were normally distributed  
 597 with a standard deviation of 30 m this method also yielded a one sigma uncertainty of  
 598  $2 \times 10^5$  m/s.

599 Larger speed uncertainties can be caused when sources are coming from multiple  
 600 branches at the same time, especially when the branches are close to each other so they  
 601 are hard to separate in the data, but these errors are typically obvious as brief extreme  
 602 fluctuations in the measured speed and can be excluded from the analysis.

## 603 Appendix B Open Research

604 All data used for this paper are placed at <https://doi.org/10.5281/zenodo.8213032>  
 605 (Jensen et al., 2023), along with some supplementary animations and figures. All data  
 606 files are in text format with headers that describe each data column. A PDF is included  
 607 which describes the included files, and gives examples of the headers and column format.

## 608 Acknowledgments

609 Research presented in this article was supported by the Laboratory Directed Re-  
 610 search and Development program of Los Alamos National Laboratory under project num-  
 611 ber 20230223ER.
